

# Impact of Hub Valley Groundwater on Scaling and Corrosion

Muhammed Kamil\*, Rashid Ali Siddiqui and Tahera Khatoon

PCSIR Laboratories Complex, Karachi-75280 Pakistan

**Abstract:** Underground water sample from the wells of Hub Valley were analysed for their physio-chemical and thermodynamic parameters to study their corrosion / scaling trend. The positive values of Langelier Saturation Index (L.S.I.) show that 90% samples are scaling, whereas, the values of Ryznar Stability Index (R.S.I.) of 95% samples that are below 7, that the most of the samples are scaling and are not corrosive. Moreover the negative values of free energy change ( $\Delta G$ ) of underground water of Hub Valley also indicate that the 90% samples are scale forming. Sample No.9 is moderately corrosive and sample No.1 is low corrosive. The water can safely be used in cooling, heating and steam generating systems after simple treatment with acids, antiscalent, water softeners etc.

**Key Words:** Corrosion, Scaling, Underground water.

## INTRODUCTION

The shortage of water in Karachi, due to rapid increase in population and industrial activity, has forced the people to meet their requirement from underground sources. Well water from Hub Valley is being supplied by tankers to various industries in Lesbela Industrial Area. Physico-chemical nature of the underground water of Korangi / Landhi was studied by Mahmood [1] and the water irrigation chemistry of the underground water in Hub Valley was studied by Qaimkhani [2]. Industry uses water as an ingredient in a finished product, as a buoyant transporting medium, as a cleaning agent, as a coolant and as a source of steam for heating and power production. The water quality requirements, for industrial processes vary greatly with the type of industry and function of the water. It is therefore not possible to set a single standard of quality for water used for varied industrial purposes. However the common industrial use of water is in cooling, heating and steam generation. The two most frequently encountered water problems in these systems are scale formation and corrosion. Corrosion / Scaling Trend of water of lower Jehelum canal was studied by Khan [3] and comparison of corrosion / scaling behaviour of water samples of Islamabad sartorial and National Park area was studied by Ahmed [4]. Minimising scale formation in pump system have been studied by DeGiorgio [5]. Langeliers Saturation Index (L.S.I) [6], is a very useful tool for the predication of corrosion / scaling behaviour of water on the metal surface. The L.S.I is applicable in the pH range of 6.5 to 9.5, Hammer [7]. Many natural waters contain soluble calcium and magnesium bicarbonates. By the addition of lime, calcium carbonate is precipitated on metal surface at an appropriate pH. The Langeliers Saturation Index (L.S.I) with respect to  $\text{CaCO}_3$  is equal to the difference between the actual measured pH of a water and  $\text{pH}_s$  at saturation with  $\text{CaCO}_3$ .

$$\text{L.S.I.} = \text{pH} - \text{pH}_s \quad 1$$

$$\text{pH}_s = \text{pCa}^{+2} + \text{pAlk} + \text{C}' \quad 2$$

Where:-  $\text{pCa}^{+2}$  = -ve log of the calcium ion concentration in mole/litre

$\text{pAlk}$  = -ve log of the total alkalinity, in equivalents/litre

$\text{C}'$  =  $\text{pK}_a - \text{pK}_s$  = constant based on ionic strength & temp.

Where:-  $\text{pka}$  = Ionisation constant of  $\text{HCO}_3^{-1}$

$\text{pks}$  = Solubility product of  $\text{CaCO}_3$

The rate of saturation with respect to calcium carbonate depends on the value of the Langelier Index as mentioned below [8]:

| Salutation | Comments                                       | Characteristic of water                  |
|------------|--|--|
| + ve       | Over saturated with respect to $\text{CaCO}_3$ | Protective film of $\text{CaCO}_3$       |
| Zero       | in equilibrium                                 | Corrosive & can dissolve $\text{CaCO}_3$ |
| - ve       | Unsaturated with respect to $\text{CaCO}_3$    |  |

Scale of LSI Hammer [7].

| L.S.I.       | EFFECT               |
|--------------|----------------------|
| > + 2.0      | High scaling         |
| +2.0 to +0.1 | Moderating scaling   |
| +0.1 to 0.0  | Low scaling          |
| 0.0 to - 0.1 | Low corrosive        |
| -0.1 to -2.0 | Moderating corrosive |
| < - 2.0      | High corrosive       |

Another index, called Ryznar Stability Index (R.S.I) was proposed by Ryznar [9] using the empirical expression.

$$\text{Rynar Stability Index} = 2\text{pHs} - \text{pH} \quad 3$$

R.S.I. < 7 Indicate a scale forming water

R.S.I. > 7 Indicate a corrosive water

This index is of particular interest in evaluating waters of widely different composition, but in any one plant if the saturation index and stability index are plotted daily on the same scale, one plot is simply the inverse of the other and has the same significance. The stability index does seem to have a particular value in predicting the performance of water when heated in hot-water heaters and coils.

The free energy ( $\Delta G$ ) change is a function of the solution alkalinity, calcium hardness and pH. As studied by Montgomery [10]. The  $\Delta G$  can influence the rate of the scaling precipitation. Positive  $\Delta G$  shows corrosion is expected whereas negative  $\Delta G$  predicts scale formation.

$$\Delta G = -(0.0045701) \times (\text{Temp } ^\circ\text{C} + 273) \times (\text{L.S.I}) \quad 4$$

### EXPERIMENT

Water samples from 20 wells were collected in thoroughly washed plastic containers for this study. The most representative sample of the area was chosen to obtain

better result. Analytical-grade (A.R) chemicals were used in the preparation of reagents. Physical and chemical analyses were carried out in triplicate for each sample and the average values were recorded. The pH value was measured immediately after collection of samples using a portable digital pH meter and all other estimations were completed within two days after sampling,  $\text{SO}_4^{-2}$  and TDS were determined by gravimetric methods,  $\text{Cl}^-$  by argentometric method.  $\text{Ca}^{+2}$  and  $\text{Mg}^{+2}$  were determined by EDTA titration method and  $\text{Na}^+$  and  $\text{K}^+$  were determined by flame photometer [1].

### RESULTS AND DISCUSSION

Water samples from the wells of Hub Valley were collected and analysed for their physico-chemical constituents. The results are tabulated in Table 1. Corrosion and scaling behaviour of the water samples were studied by analysing their thermodynamic parameters. The results are tabulated in Table 2.

The pH values were in the range of 6.59 to 8.26. This shows that Langelier Saturation index is applicable for all the samples. The pHs of 90% samples is lower than pH, hence the L.S.I. is positive in these cases, which reveals that the

underground water of Hub Valley is scaling in nature and the scaling of 65% samples is in moderate range. The corrosion / scaling trend of underground water of Hub Valley on the basis of L.S.I. values is graphically shown in Fig. (1).

The values of Ryznar Stability Index of all the water samples except sample number 9 lie below 7. This also

indicates that this underground water of Hub Valley is scale forming not corrosive Fig. (2) depicts these results.

The values of free energy change  $\Delta G$  were also calculated. 90% values are on negative side, which further indicates that the underground water of Hub Valley is scale forming. Only sample No.1&9, are low and moderately

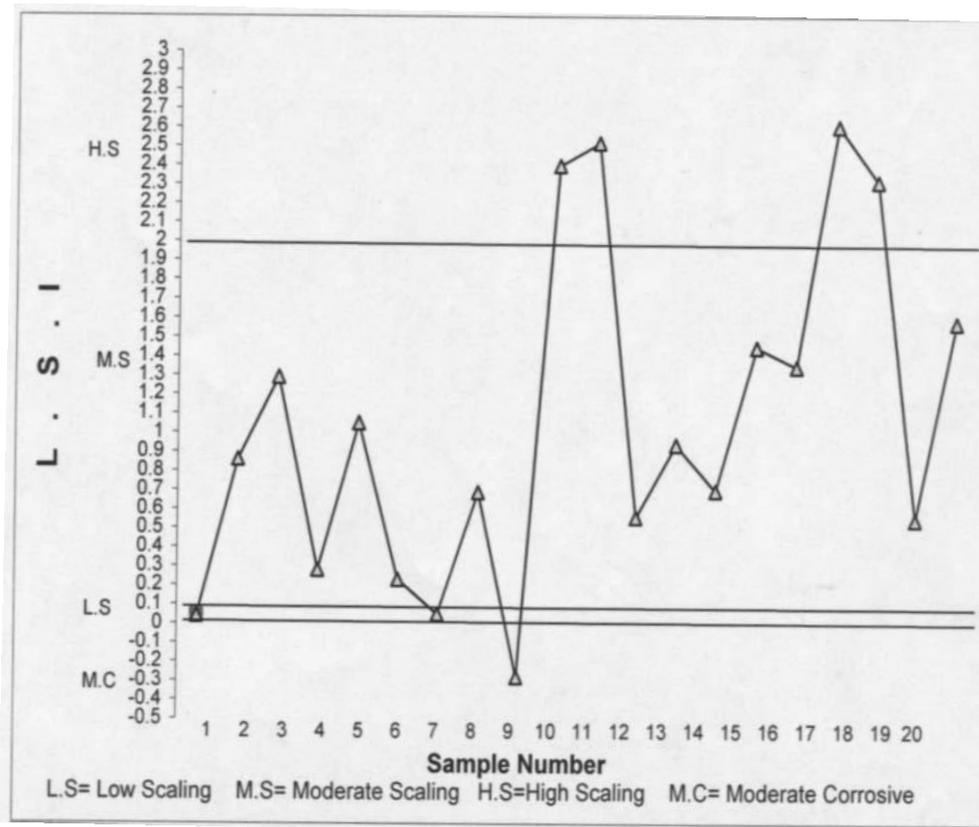

Fig. (1). Corrosive/scaling trend of under groundwater of Hub Valley on the basis of L.S.I. values.

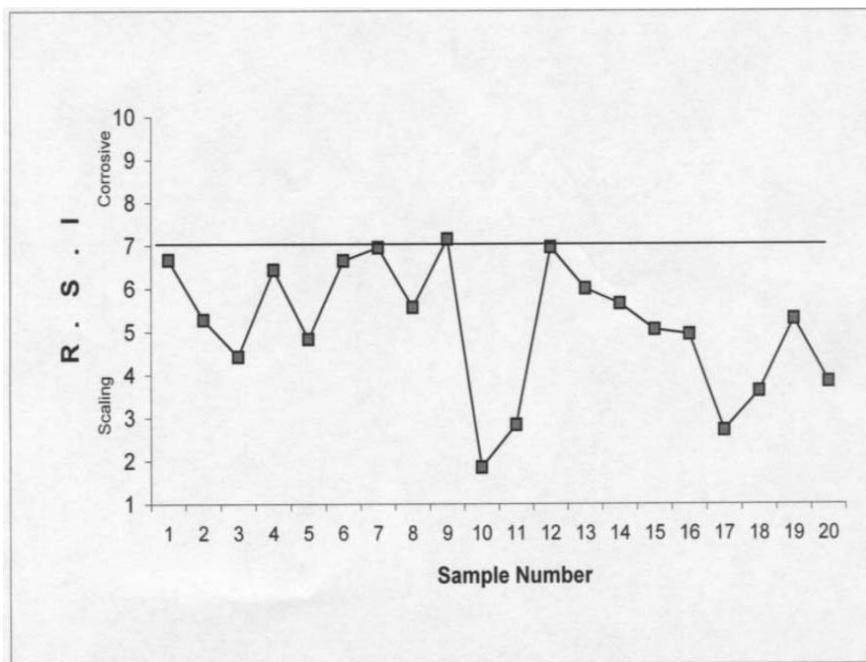

Fig. (2). Corrosive/scaling trend of under groundwater of Hub Valley on the basis of R.S.I. values.

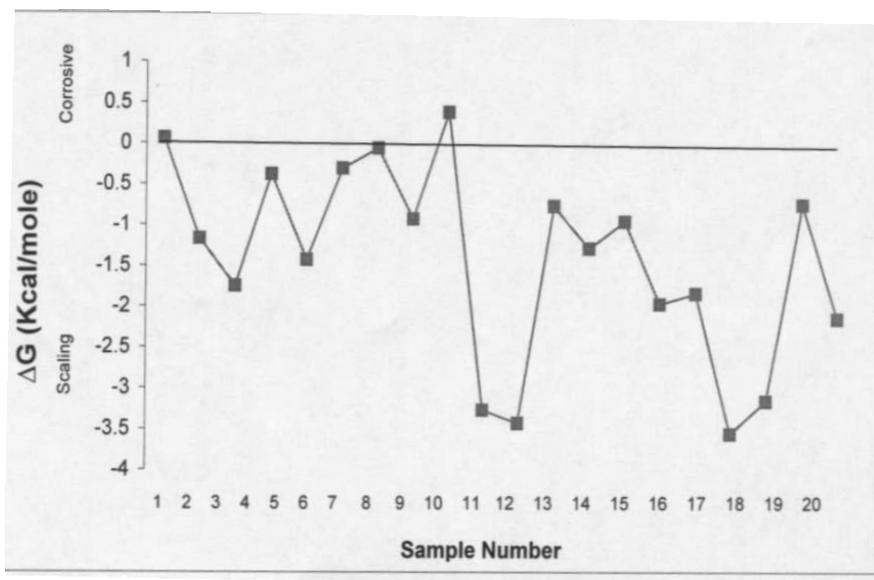

Fig. (3). Corrosive/scaling behaviour of underground water of Hub Valley on the basis of free energy ( $\Delta G$ )

corrosive respectively. All other samples are scale forming in nature. These results are graphically shown in Fig. (3).

Small amount of scale formation is not always a bad thing. In some cases, a thin layer of  $\text{CaCO}_3$  scale helps to inhibit corrosion. Moreover, viable treatment alternatives to prevent scale formation or remove existing scale, includes acid neutralization, chemical antiscalents, water softening devices and magnetic flow through or non-intrusive devices DeGiorgio [5].

**CONCLUSION**

Analysis of thermodynamic parameters reveals that the underground water of Hub Valley is scale forming in nature. However it can safely be used by applying viable treatment alternatives.
